Figure 1: Location map.

INTRODUCTION

Objectives

An aggregate inventory was carried out for the Local Government District of Reynolds during the summers of 1984, 1985 and 1986. The objectives were to delineate sand and gravel deposits at a scale of 1:50 000 and to estimate the quantity and quality of material in each deposit. The aggregate inventory information would then provide a database for landuse planning and potential resource users.

Location and Access

The Local Government District of Reynolds is located 43 km east of Winnipeg via PTH 15 or 49 km east via PTH 1. It comprises 37 townships (3450 km²), including a large portion of townships 5-13 ranges 9-15E (Fig. 1). The area is included on NTS map sheets; 52E, 52L, 62H and 62I.

A network of provincial roads, fire roads and trails provide access to much of the Local Government District of Reynolds. However, vast undeveloped areas, commonly swamp, are inaccessible.

Provincial Trunk Highways 1, 11, 15 and 44 transect the area and provide good access to major centres. The Local Government District boundaries encompass the major portion of the Agassiz, Sandilands and Whiteshell Provincial forests; a network of fire roads and trails has been created for forest management purposes. These forestry roads provide good access, but would generally require upgrading for truck traffic transporting aggregate.

Physiography

The eastern third of the L.G.D. of Reynolds is primarily Precambrian bedrock and swamp. Local relief is generally less than 5m. The bedrock surface slopes westward, from approximately 340m in the east to 240m in the west and plunges beneath glacial drift and paleozoic bedrock.

The area west of the Canadian Shield ranges in elevation from 250m in the northwest to 380m in the southwest. The Milner Ridge-Bedford Hills Moraine trends southward from Seddons Corner (Fig. 1). This moraine rises as much as 50m above the surrounding landscape.

The moraine system is broken in townships 9 through 11 by several southeast trending ridges. These ridges are low and broad and bounded by swamp.

The depth to bedrock increases westward from the Canadian Shield to approximately 30m. This trend is broken in the area of the Milner Ridge - Bedford Hills Moraine where the depth to bedrock increases southward to a maximum of approximately 120m (Teller et al., 1976).

Drainage of the area is to the north. The Canadian Shield portion of the L.G.D. of Reynolds is drained by the Whitemouth River system which includes the tributaries of Birch, Boggy and Bog rivers. Except for a small area (approximately 80 square km.) in the southwest corner, which

is in the Seine River watershed, the remainder of the area is drained by the Brokenhead River system.

Hazel Creek, the major tributary of the Brokenhead River, has the unusual distinction of having had a portion of its watershed captured by the Whitemouth River. Two kilometres north of Hadashville, Hazel Creek branches off to the northwest. The first several kilometres of Hazel Creek channel west of the Whitemouth River are abandoned.

Methodology

Prior to field investigation potential aggregate deposits were delineated on 1:50 000 airphotos incorporating: air-photo interpretation of black and white photographs at a scale of 1:50 000 and 1:15 840; information from pit inventory files of the Department of Highways and Transportation; and soils maps (Smith and Ehrlich, 1964; Smith and Ehrlich, 1967).

Field investigation was conducted over three field seasons commencing in the summer of 1984. The work started in the north and generally proceeded southward. All existing exposures, including gravel pits and road cuts, were visited and samples were collected from deposits considered to be of economic value. Sites believed to have unproven aggregate potential were backhoe tested in the latter portion of each field season.

Gravel samples collected in the summers of 1984 and 1985 weighed between 15 and 20 kg; the maximum grain size sampled was 76 mm (3 inches). During the winter of 1985 a new sampling procedure was developed to overcome sampling deficiencies in deposits with an abundance of material coarser than 19.1 mm (3/4 inch). At the same time the nest of screens used for grain size analysis was reduced from 22 to 11 screens (Fig. 2).

The new sampling procedure involved field screening using 3 inch (76 mm), 1 1/2 inch (38 mm) and 3/4 inch (19 mm) screens. Stones retained on the 1 1/2 inch and 3/4 inch screens were weighed in the field and a representative sample of the material passing the 3/4 inch screen was obtained for laboratory processing. This procedure made possible samples up to 150 kg when necessary (ASTM D75-82, 1987).

Petrographic analysis was performed on the 4-16 mm size fraction. Pebbles were divided into Paleozoic and Precambrian lithologies. Deleterious lithologies and weathered clasts were noted when present.

Field data and aggregate deposit boundaries were plotted on 1:15 840 scale airphotos and these were used to produce the 1:50 000 scale maps accompanying this report. Where detailed backhoe testing was carried out on regional significant gravel deposits, the 1:50 000 map scale is not adequate to reproduce the detail. These deposits (2184B and C, 3760B, 3767F and 2871A-L) are highlighted on the 1:50 000 maps and detailed on airphoto mosaic inserts on the appropriate mapsheets at a scale of 1:15 840.

Figure 2: Grain size analysis and classification.

Previous Work

Much of the L.G.D. of Reynolds has been mapped prior to this study and where possible this information has been integrated into this study. Smith and Ehrlich (1964 and 1967) mapped the surface deposits as part of the regional soil survey; the northern portion of the area as part of the Lac du Bonnet area (Report No. 15) and the south as part of the south-eastern sheet (Report No. 14). Nielsen (1987) mapped the northeast corner of the L.G.D. of Reynolds and defined the eastern margin of calcareous glacial sedimentation as a northwest trending line across that corner of the L.G.D. of Reynolds. Many of the deposits have been backhoe tested by Materials and Research Branch of the Manitoba Department of Highways and Transportation.

Preliminary studies by the Mines Branch covered the western townships of the area; Ringrose et al. (1977) recognized the importance of the Seddons Corner area and during their preliminary work generated a detailed study of the Seddons Corner deposit (Ringrose and Large; unpub.).

They strongly recommended that the Seddons Corner aggregate supply be protected for the Winnipeg market addressing the potential aggregate shortage in proximity to Winnipeg.

Underwood McLellan and Associates (1976) also recognized the importance of the western portion of the L.G.D. of Reynolds to the Winnipeg market area. They stressed that after the Birds Hill area the next significant aggregate source is the Belair-Agassiz-Sandilands Forest Reserves; a hauling distance to Winnipeg of 50-80 km.

Acknowledgements

Many areas, particularly in the north, were backhoe tested in conjunction with Materials and Research Branch of the Manitoba Department of Highways. Ivan du Plessis provided able field assistance; M. Carvalho drafted the maps and figures, M. Bouttell typed the text, and S. Weselak formatted the report.

BEDROCK GEOLOGY

Archean rocks of the Precambrian shield outcrop extensively throughout the eastern third of the map area. This complex sequence of intrusive rocks comprise primarily granite and granodiorite with lesser amounts of gneiss, migmatite and basalt (Manitoba Department of Mines, Resources and Environment, 1979).

The Ordovician Winnipeg Formation subcrops in range 9E, generally following the western boundary of the

map area (Fig. 1). The Winnipeg Formation is primarily quartzose sandstone interbedded with shale. The Winnipeg Formation subcrop belt separates the Ordovician Red River Formation to the west from the Archean rocks of the Precambrian shield. The Red River Formation is predominantly dolomitic limestone (Manitoba Department of Mines, Resources and Environment, 1979).

LATE WISCONSINAN HISTORY

Late Wisconsinan stratigraphy and history of the R.M. of Lac du Bonnet and the L.G.D. of Alexander, directly north of the L.G.D. of Reynolds, was discussed in detail by Matile and Groom (1987) and due to the similarities will not be discussed here. Surficial mapping in the L.G.D. of Reynolds suggests that, in addition to events depicted by Matile and Groom (1987), a late glacial event, possibly a surge, advanced into Lake Agassiz and transected the L.G.D. of Reynolds.

The area affected by the late glacial surge is defined by landform style and sediment lithology. Landforms within the area affected by the surge are strongly streamlined parallel to ice flow; deposits 3767, 3781, and the area of and between 3754 and 3760 are good examples (Map AR80-2-1). Streamlining of the area around deposit 3760 can clearly be seen in Detail C (Map AR89-2-1); ice flow was from the northwest. The area comprising deposits 2119, 2120, 2147, 2159, 2160 and 2163 is also streamlined and within the area affected by the surge.

The ice marginal position is defined by deposits 2124, 2184, 3748, 3756 and probably extends southward along the northwest edge of deposit 2111 (the northwest facing

escarpment) (Map AR89-2-1 and 3). An outwash fan (deposits 2189 and 2195) was formed at this ice margin by large volumes of glacial meltwater emanating from the subglacial channel defined between deposits 3754 and 3760. Granular facies exposed in the southern portion of the Bedford Hills Moraine (Fig. 1) suggest that much of the moraine may have been built at this time.

In addition to a change in landform style, the northeast margin, the lateral margin of the surge, is defined by a dramatic change in sediment lithology. Deposit 3783, 3789 and 3793 (Map AR89-2-1) contain highly variable sediment lithologies, ranging from 85% Paleozoic lithologies to 80% Precambrian lithologies (Table 1) and represent an area of transition. They were probably overridden, but due to their proximity to the ice margin, were only partially modified. Deposit 2871 has not been affected by the surge. It's pristine, Precambrian-rich (averaging 78% Precambrian lithologies) landforms were deposited by an earlier advance of the Rainy Lobe (Matile and Groom, 1987). The only other deposits where Precambrian lithologies dominate are deposits 3730 (Map AR89-2-2) and 3785 (Map AR89-2-4).

	Criteria	High	Medium	Low
AGGREGATE QUALITY	Stone %	30	15-30	0-15
	Sand %	0-35	35-70	70

	Aggregate Substitute	none	marginal	proximal

Figure 3: Aggregate quality and development potential guidelines. *Note: These guidelines are an attempt to classify deposits in a broad spectrum of areas throughout Manitoba. Importance of individual criteria varies greatly depending on availability of aggregate within each region.*

AGGREGATE RESOURCES

Aggregate reserves were calculated on a per-quarter-section basis, taking into account proven depths and the amount of depletion and sterilization. Sample and deposit quality were established using the guidelines set out in Figure 3.

Deposit reserves, exposure information and grain size distribution of aggregate samples are included in Table 1. This information correlates to the aggregate maps by: 1) deposit number, 2) exposure number, and 3) legal description.
